

METHOD FOR THE PRODUCTION OF EXPANDABLE PLASTICSGRANULATE

Insert q1
Insert qa
Insert q3

The invention relates to a method for the production of expandable plastics granulate and equipment and plant for carrying out or using the method.

9 An often used foamed plastics is made of polystyrene. In this process granulate of "expandable polystyrene", EPS, is processed into blocks or ^{molded} ~~moulded~~ parts, while in an intermediate step the granulate is prefoamed. EPS may be manufactured by suspension polymerization. In that process styrene is polymerized in an aqueous phase with the addition of a blowing agent. In this way a bead-shaped granulate is produced within a wide range of bead sizes. A disadvantage of this method is that large quantities of water, which must be cleaned, accumulate and that the granulate is usable for the production of the foamed material only within a limited range of sizes so that a considerable part of the produced polymer must be discarded (or recycled).

20 In another method, which is little suitable for the production of large quantities of EPS, the polystyrene is, after polymerization, impregnated by a blowing agent in pressure vessels or in extruders. The product is cylindrical granulate.

25 Further information on foamed materials can be found in Ullmanns Encyklopädie der technischen Chemie (4th edition, 1981), volume 20, pages 415 to 432 and volume 19, pages 268 and 131.

Insert q5

The aim of the invention is to provide a method of economical production of expandable plastics granulate,

for instance of EPS, by which may be produced large quantities without the disadvantages of the known methods. According to this method a plastics melt is impregnated with a fluid blowing agent which is, at
 5 elevated pressure within a given pressure region, only partially soluble in the melt. ~~This aim is achieved by the method having characterising features stated in Claim~~
 10 ~~1. The method may be carried out using equipment according to claim 6 or a plant according to claim 11. A preferred use of such plant (or equipment or method) is in the production of EPS (claim 15).~~

Large quantities of EPS or another comparable granulate cannot be economically produced by extruders, because a plurality of extruders used in parallel would have to be
 15 used. The use of the equipment according to the invention, in which the impregnation of the plastics melt may be carried out in a single apparatus, represents an economical advantage. The teaching of the invention is based substantially on the discovery that large
 20 quantities of expandable plastics granulate may be produced in an apparatus only if provisions against segregation of the melt and blowing agent are possible and are made. According to the invention, static mixing elements act during the whole course of the process
 25 continuously onto the mixture in such a way that segregation is avoided.

Compared with the known methods using extruders, the method according to the invention has the further advantage that much less energy - about one order less -
 30 is needed for the production of expandable plastics granulate. With this advantage is connected a second one, namely that there is a smaller temperature rise during the impregnation and consequently less heat need

be dissipated.

a ~~The dependent claims 2 to 4 relate to advantageous embodiments of the method according to the invention. They relate in detail to an efficient method for the impregnation of the plastics melt by the blowing agent, a simple method for the cooling of the impregnated mixture and a useful method of granulation. By the feature of~~

9 ~~claim 5, namely addition not only of a blowing agent but also several additives to the melt, the quality of the product can be advantageously influenced. As a blowing agent~~
9 ~~is used a chlorofluorocarbon or preferably a low-boiling hydrocarbon, particularly pentane, or a mixture of such hydrocarbons.~~
9 ~~As additives may be used~~

10 ~~flameproofing agents (compounds of bromine), lubricants (oil, derivatives of stearic acid), dyes, antioxidants,~~
9 ~~softeners or nucleators (for the formation of cells).~~
15 ~~may be used~~

20 ~~The dependent claims 7 to 10 relate to advantageous embodiments of the equipment according to the invention and the dependent claims 12 to 14 relate to various possible applications of the plant according to the invention.~~

9 ~~The invention will now be explained in greater detail with reference to the drawings. In the drawings:~~

25 Fig. 1 is a block diagram for the explanation of the plant or method according to the invention,

9 Fig. 2 ~~is a graph illustrating the~~
~~shows qualitatively represented~~ course of the pressure p for the equipment according to the invention,

9 Fig. 3 ~~is a graph illustrating~~
~~shows~~ the course of pressure in a second \

embodiment
equipment, and

Fig. 4 is a diagram ^{illustrating} for a plant for the production of EPS according to the invention.

In the block diagram of Fig. 1 the reference numerals 1 to 4 relate to ~~the~~ four method steps, ~~referred to in the~~ ^{these} preamble of claim 1: dispersion 1, retention 2, cooling 3 and granulation 4. ~~To these~~ ^{These} method steps correspond in the pressure diagrams of ~~Figures~~ ^{Figs.} 2 and 3 ^{to} the intervals I, II, III, IV. Because the individual blocks of the diagram in Fig. 1 are interpreted as parts of the plant, the same references may be used for the plant parts in Fig. 4 as in the block diagram. In Fig. 1 ~~are~~ ^{are} these plant parts 1, 2, 3, and 4 arranged linearly in the direction of the x-axis. The raw materials for the method are a plastics A (or a monomer A) and a blowing agent B (possibly with the addition of one or more additives); the product is the expandable plastics granulate C to be produced.

Fig. 1 shows - interpreted as a plant - the following parts: a source 10 of plastics with a tank 9 for A and a device 11 in which is produced a gas-free plastics melt A'; a source 20 of blowing agent with a tank 19 containing B and a device 21 by means of which B can be metered; a control unit 30 by means of which the amount of B can be adjusted to the amount of A'; and finally the equipment 1, 2, 3, 4, in which is carried out the method according to the invention.

In the dispersion step 1 the melt A' is mixed at elevated pressure with the blowing agent B, the melt being subjected to extensive shearing so that the liquid blowing agent is dispersed in the melt in the form of

9 fine droplets. During a predetermined retention time in
 the step 2, the blowing agent partly diffuses in the
 melt. Impregnation, which is carried out in both the
 first two steps, proceeds preferably at a temperature
 5 which lies considerably above the solidification
 9 temperature of the melt. ~~Because the~~ ^{The} higher the
 temperature ^{means} the smaller the viscosity of the melt and ^{therefore} the
 9 better ~~proceeds~~ the distribution of the blowing agent. ^{proceeds}

9 10 In the cooling step 3 the temperature of the melt ^{degrees Celsius}
 impregnated by the blowing agent is reduced several ^{°C}
 above the solidification temperature of the melt. The
 cooled mixture is then in the last step 4 transformed to
 granulate form.

15 To avoid any segregation during the passage through the
 equipment 1, 2, 3, 4, the mixture is kept in motion in
 all method steps and also during transfer from one step
 to the next; this is achieved, according to the
invention, by using static mixing elements.

20 The source 10 of plastics may contain a polymerization
 reactor for the production of the plastics A' from a
 monomer raw material A and also a degassifier for the
 polymer. The source 10 of plastics may also include a
 recycling device for the recycling of the thermoplastic
 and a melting device. The thermoplastic should be
 25 preferably of the same kind. Also a melting device for a
 granular thermoplastic may be used as a source of
 plastics. For instance a heatable extruder may be used as
the melting device.

30 Fig. 2 shows qualitatively the course of pressure p in
 the four method steps. During the dispersion, interval I,
 the pressure drop is due to the extensive shearing ^{being}

relatively large compared with the pressure drop in the second step, interval II. The cooling, interval III, takes place again with a larger pressure drop which is the result of provisions for achieving efficient heat exchange. During the granulation step, interval IV, the mixture is extruded through nozzles while the pressure sharply drops. So as to avoid expansion of the formed strands by the blowing agent, the extruded mixture must be abruptly cooled by a coolant, preferably water.

Between the steps 1 and 2 and/or steps 2 and 3 may be provided pumps by means of which the pressure is again increased. This is shown in Fig. 3, where the intervals I' and II' are associated with such provisions.

In the embodiment shown in Fig. 4 the source 10 of plastics is formed by a polymerization reactor 12 for the production of polystyrene from the monomer raw material A' (styrene), by a degassifier 14 for the polymer and two gear pumps 13 and 15. The blowing agent B' (for instance n-pentane) is fed ^{from source 20} to the melt A" by a metering piston pump 21'.

The impregnation is performed in the unit 1', 2' at an initial pressure of e.g. 100 bar (= 10 MPa) and a temperature of about 200 °C. This unit preferably

contains a first static mixer, a "shearing mixer" 1' for the dispersion of the blowing agent and a second static mixer, a "retention time mixer" 2', situated immediately next to the first one and serving for diffusive transport of the blowing agent into the melting phase. (The two mixers 1' and 2' are not shown in Fig. 4 as components.)

In the shearing mixer 1' ^{is performed} the dispersion with more intensive shearing of the melt while fine droplets of the blowing agent are formed. The intensive shearing

is achieved by a high flow rate. In the retention time mixer 2' the mixture is subjected, during a retention time needed for the diffusive transport, to little shearing. The uneven flowing conditions in the two mixers are obtained in that the second mixer is made with a much larger cross-sectional area than the first one.

A gear pump 5 pumps the impregnated melt into the unit 3' in which is combined mixing by static means with heat exchange. Preferably a device known from DE A 28 39 564 is used, namely a static mixer whose crossing elements are made as heat exchange pipes. The pressure drop is, for instance, 100 bar and the initial temperature about 120 °C. As a cooler ~~may be used, for instance,~~ a heat exchanger containing a bundle of pipes ^{may be used} in whose individual pipes are provided with static mixing elements.

Finally the impregnated and cooled melt is in a strand granulator 4', which contains a nozzle plate ⁴¹, a cooling bath 43 and a cutting device 42 ~~bath and a cutting device (not shown)~~, converted into the desired product C', namely EPS. The pressure drop upstream of the nozzle plate is at least 10 bar. As a cooling bath ~~is used~~ a cooling water bath (about 10 °C) ^{is used}. The strands emerging from the nozzles (diameter smaller than 1 mm) are first cooled and finally cut by a cutter with several blades. The product is a granulate with granulate grains of uniform size. As a consequence - in contrast to the suspension polymerization mentioned at the beginning - the whole product may be used for the production of foamed plastics.

As a granulation device may be used, apart from the strand granulator, ^{and} also a hot strand chopping granulator or a so-called underwater granulator ^{may also be used}. In the underwater

9

granulator ~~may be made~~ ⁸ *maybe made* granulate whose grains have practically the same shape as the granulate grains produced by suspension granulation.
